WISC-SP13 Microarchitecture Specification

The WISC-SP13 architecture that you will design for the final project shares many resemblances with the MIPS R2000 described in the textbook. The major differences are a smaller instruction set and 16-bit words for the WISC-SP13. Similarities include a load/store architecture and three fixed-length instruction formats.

Registers

There are eight user registers, R0-R7. Unlike the MIPS R2000, R0 is not always zero. Register R7 is used as the link register for JAL or JALR instructions. The program counter is separate from the user register file. A special register named EPC is used to save the current PC upon an exception or interrupt invocation.

Memory System

The WISC-SP13 is a Harvard architecture, meaning instructions and data are located in different physical memories. It is byte-addressable, word aligned* (where a word is 16 bits long), and big-endian. The final version of the WISC-SP13 will include a multi-cycle memory and level-1 cache. However, initial versions of the machine will contain a single cycle memory. (More details will be provided as reach the corresponding stage)

Pipeline

The final version of the WISC-SP13 contains a five stage pipeline identical to the MIPS R2000. The stages are:

- Instruction Fetch (IF)
- Instruction Decode/Register Fetch (ID)
- Execute/Address Calculation (EX)
- Memory Access (MEM)
- Write Back (WB)

Optimizations

Your goal in optimizations is to reduce the CPI of the processor or the total cycles taken to execute a program. While the primary concern of the WISC-SP13 is correct functionality, the architecture must still have a reasonable clock period. Therefore, you may not have more than one of the following in series during any stage:

- register file
- memory or cache
- 16-bit full adder
- barrel shifter

You may implement any type of optimization to reduce the CPI. The required optimizations are:

- There are two register forwarding paths in the WISC-SP13; one within the ID stage and between the beginning of MEM and the beginning of EX.
- All branches should be predicted not-taken. This means that the pipeline should continue to execute sequentially until the branch resolves, and then squash instructions after the branch if the branch was actually taken.

Exceptions: extra credit

Exception handling is extra credit. If you choose not to implement exception handling, an illegal instruction should be treated as a nop.

IllegalOp is the only defined exception in the WISC-SP13 architecture. It is invoked when the opcode of the currently executing instruction is not a recognized member of the ISA. Upon finding an illegal opcode, the computer shall save the current PC into the reserved register EPC and then load address 0x02, which is the location of the IllegalOp exception handler. Note that if you choose to implement exceptions, address 0x00 must be a jump to the start of the main program.

The exception handler itself need not be complex. At a minimum it should load the value 0xBADD into R7 and then call the RTI instruction.

WISC-SP13 Instruction Set Architecture Specification

Instructions Summary

Instruction Format	Syntax	Semantics
00000 xxxxxxxxxxx	HALT	Cease instruction issue, dump memory state to file
00001 xxxxxxxxxxx	NOP	None
01000 sss ddd iiiii	ADDI Rd, Rs, immediate	Rd <- Rs + I(sign ext.)
01001 sss ddd iiiii	SUBI Rd, Rs, immediate	Rd <- I(sign ext.) - Rs
01010 sss ddd iiiii	XORI Rd, Rs, immediate	Rd <- Rs XOR I(zero ext.)
01011 sss ddd iiiii	ANDNI Rd, Rs, immediate	Rd <- Rs AND ~I(zero ext.)
10100 sss ddd iiiii	ROLI Rd, Rs, immediate	Rd <- Rs <<(rotate) I(lowest 4 bits)
10101 sss ddd iiiii	SLLI Rd, Rs, immediate	Rd <- Rs << I(lowest 4 bits)
10110 sss ddd iiiii	RORI Rd, Rs, immediate	Rd <- Rs >>(rotate) I(lowest 4 bits)
10111 sss ddd iiiii	SRLI Rd, Rs, immediate	Rd <- Rs >> I(lowest 4 bits)
10000 sss ddd iiiii	ST Rd, Rs, immediate	Mem[Rs + I(sign ext.)] <- Rd
10001 sss ddd iiiii	LD Rd, Rs, immediate	Rd <- Mem[Rs + I(sign ext.)]
10011 sss ddd iiiii	STU Rd, Rs, immediate	Mem[Rs + I(sign ext.)] <- Rd Rs <- Rs + I(sign ext.)
11001 sss xxx ddd xx	BTR Rd, Rs	Rd[bit i] <- Rs[bit 15-i] for i=0..15
11011 sss ttt ddd 00	ADD Rd, Rs, Rt	Rd <- Rs + Rt
11011 sss ttt ddd 01	SUB Rd, Rs, Rt	Rd <- Rt - Rs
11011 sss ttt ddd 10	XOR Rd, Rs, Rt	Rd <- Rs XOR Rt
11011 sss ttt ddd 11	ANDN Rd, Rs, Rt	Rd <- Rs AND ~Rt
11010 sss ttt ddd 00	ROL Rd, Rs, Rt	Rd <- Rs << (rotate) Rt (lowest 4 bits)

11010 sss ttt ddd 01	SLL Rd, Rs, Rt	Rd <- Rs << Rt (lowest 4 bits)
11010 sss ttt ddd 10	ROR Rd, Rs, Rt	Rd <- Rs >> (rotate) Rt (lowest 4 bits)
11010 sss ttt ddd 11	SRL Rd, Rs, Rt	Rd <- Rs >> Rt (lowest 4 bits)
11100 sss ttt ddd xx	SEQ Rd, Rs, Rt	if (Rs == Rt) then Rd <- 1 else Rd <- 0
11101 sss ttt ddd xx	SLT Rd, Rs, Rt	if (Rs < Rt) then Rd <- 1 else Rd <- 0
11110 sss ttt ddd xx	SLE Rd, Rs, Rt	if (Rs <= Rt) then Rd <- 1 else Rd <- 0
11111 sss ttt ddd xx	SCO Rd, Rs, Rt	if (Rs + Rt) generates carry out then Rd <- 1 else Rd <- 0
01100 sss iiiiiiii	BEQZ Rs, immediate	if (Rs == 0) then PC <- PC + 2 + I(sign ext.)
01101 sss iiiiiiii	BNEZ Rs, immediate	if (Rs != 0) then PC <- PC + 2 + I(sign ext.)
01110 sss iiiiiiii	BLTZ Rs, immediate	if (Rs < 0) then PC <- PC + 2 + I(sign ext.)
01111 sss iiiiiiii	BGEZ Rs, immediate	if (Rs >= 0) then PC <- PC + 2 + I(sign ext.)
11000 sss iiiiiiii	LBI Rs, immediate	Rs <- I(sign ext.)
10010 sss iiiiiiii	SLBI Rs, immediate	Rs <- (Rs << 8) | I(zero ext.)
00100 ddddddddddd	J displacement	PC <- PC + 2 + D(sign ext.)
00101 sss iiiiiiii	JR Rs, immediate	PC <- Rs + I(sign ext.)
00110 ddddddddddd	JAL displacement	R7 <- PC + 2 PC <- PC + 2 + D(sign ext.)
00111 sss iiiiiiii	JALR Rs, immediate	R7 <- PC + 2 PC <- Rs + I(sign ext.)
00010	siic Rs	produce IllegalOp exception. Must provide one source register.
00011 xxxxxxxxxxx	NOP / RTI	PC <- EPC

Formats

WISC-SP13 supports instructions in four different formats: J-format, 2 I-formats, and the R-format. These are described below.

J-format

The J-format is used for jump instructions that need a large displacement.

J-Format

```
5 bits      11 bits
Op Code     Displacement
```

Jump Instructions
The Jump instruction loads the PC with the value found by adding the PC of the next instruction (PC+2, not PC+4 as in MIPS) to the sign-extended displacement.

The Jump-And-Link instruction loads the PC with the same value and also saves the address of the next sequential instruction (i.e., PC+2) in the link register R7.

The syntax of the jump instructions is:

- J displacement
- JAL displacement

I-format

I-format instructions use either a destination register, a source register, and a 5-bit immediate value; or a destination register and an 8-bit immediate value. The two types of I-format instructions are described below.

I-format 1 Instructions

I-format 1

```
5 bits      3 bits      3 bits      5 bits
Op Code     Rs          Rd          Immediate
```

The I-format 1 instructions include XOR-Immediate, ANDN-Immediate, Add-Immediate, Subtract-Immediate, Rotate-Left-Immediate, Shift-Left-Logical-Immediate, Rotate-Right-Immediate, Shift-Right-Logical-Immediate, Load, Store, and Store with Update.

The **ANDNI** instruction loads register Rd with the value of the register Rs AND-ed with the **one's complement** of the zero-extended immediate value. (It may be thought of as a bit-clear instruction.) **ADDI** loads register Rd with the sum of the value of the register Rs plus the

ALU_Op = 00, Zero/sign = Sign, Cin = 1, InvA = 1

sign-extended immediate value. **SUBI** loads register Rd with the result of subtracting register Rs from the **sign-extended** immediate value. (That is, immed - Rs, **not** Rs - immed.) Similar instructions have similar semantics, i.e. the logical instructions have zero-extended values and the arithmetic instructions have sign-extended values.

For Load and Store instructions, the effective address of the operand to be read or written is calculated by adding the value in register Rs with the **sign-extended** immediate value. The value is loaded to or stored from register Rd. The **STU** instruction, Store with Update, acts like Store but also writes Rs with the effective address.

Rd Sel = 10, mem_WE = 0

The syntax of the I-format 1 instructions is:

- ADDI Rd, Rs, immediate
- SUBI Rd, Rs, immediate
- XORI Rd, Rs, immediate
- ANDNI Rd, Rs, immediate
- ROLI Rd, Rs, immediate
- SLLI Rd, Rs, immediate
- RORI Rd, Rs, immediate
- SRLI Rd, Rs, immediate
- ST Rd, Rs, immediate
- LD Rd, Rs, immediate
- STU Rd, Rs, immediate

I-format 2 Instructions

I-format 2

```
5 bits      3 bits      8 bits
Op Code     Rs          Immediate
```

The Load Byte Immediate instruction loads Rs with a sign-extended 8 bit immediate value.

The Shift-and-Load-Byte-Immediate instruction shifts Rs 8 bits to the left, and replaces the lower 8 bits with the immediate value.

The format of these instructions is:

- LBI Rs, signed immediate
- SLBI Rs, unsigned immediate

The Jump-Register instruction loads the PC with the value of register Rs + signed immediate. The Jump-And-Link-Register instruction does the same and also saves the return address (i.e., the address of the JALR instruction plus one) in the link register R7. The format of these instructions is

- JR Rs, immediate
- JALR Rs, immediate
-

The branch instructions test a general purpose register for some condition. The available conditions are: equal to zero, not equal to zero, less than zero, and greater than or equal to zero. If the condition holds, the signed immediate is added to the address of the next sequential instruction and loaded into the PC. The format of the branch instructions is

- BEQZ Rs, signed immediate
- BNEZ Rs, signed immediate
- BLTZ Rs, signed immediate
- BGEZ Rs, signed immediate

R-format

R-format instructions use only registers for operands.

R-format

```
5 bits      3 bits      3 bits      3 bits      2 bits
Op Code     Rs          Rt          Rd          Op Code Extension
```

ALU and Shift Instructions
The ALU and shift R-format instrucions are similiar to I-format 1 instructions, but do not require an immediate value. In each case, the value of Rt is used in place of the immediate. No extension of its value is required. **In the case of shift instructions, all but the 4 least-significant bits of Rt are ignored**.

The ADD instruction performs signed addition. The SUB instruction subtracts Rs from Rt. (Not Rs - Rt.) The set instructions SEQ, SLT, SLE instructions compare the values in Rs and Rt and set the destination register Rd to 0x1 if the comparison is true, and 0x0 if the comparison is false. SLT checks for Rs less than Rt, and SLE checks for Rs less than or equal to Rt. (Rs and Rt are two's complement numbers.) The set instruction SCO will set Rd to 0x1 if Rs plus Rt would generate a carry-out from the most significant bit; otherwise it sets Rd to 0x0. The Bit-Reverse instruction, BTR, takes a single operand Rs and copies it to Rd, but with a left-right reversal of each bit; i.e. bit 0 goes to bit 15, bit 1 goes to bit 14, etc.

The syntax of the R-format ALU and shift instructions is:

- ADD Rd, Rs, Rt
- SUB Rd, Rs, Rt
- ANDN Rd, Rs, Rt
- ROL Rd, Rs, Rt
- SLL Rd, Rs, Rt
- ROR Rd, Rs, Rt
- SRL Rd, Rs, Rt
- SEQ Rd, Rs, Rt
- SLT Rd, Rs, Rt
- SLE Rd, Rs, Rt
- SCO Rd, Rs, Rt

- BTR Rd, Rs

Special Instructions

Special instructions use the R-format. The HALT instruction halts the processor. The HALT instruction and all older instructions execute normally, but the instruction after the halt will never execute. The PC is left pointing to the instruction directly after the halt.

The No-operation instruction occupies a position in the pipeline, but does nothing.

The syntax of these instructions is:

- HALT
- NOP

The SIIC and RTI instructions are extra credit and can be deferred for later. They will be not tested until the final demo.

The SIIC instruction is an illegal instruction and should trigger the exception handler. EPC should be set to PC + 2, and control should be transferred to the exception handler which is at PC 0x02.

The syntax of this instruction is:

- SIIC Rs

The source register name must be ignored. The syntax is specified this way with a dummy source register, to reuse some components from our existing assembler. The RTI instruction should remain equivalent to NOP until the rest of the design has been completed and thoroughly tested.

RTI returns from an exception by loading the PC from the value in the EPC register.

The syntax of this instruction is:

- RTI
